

# IPv6 Addressing

CSCI 101

# IPv6

- 1990s - addressing limitations of IPv4
- 1994 Internet Engineering Task Force (IETF)

# IPv4 vs IPv6

## IPv4:

- Running out of IP addresses (Class A and B waste lots of hosts)
- IPv4 IPSec optional
- IPv4 supports unicast (1-1), broadcast (1-all), multicast (1-many)

## IPv6:

- IPv6 uses 128-bit addresses ( $3.4 \times 10^{38}$ )
- IPv6: IPSec support is mandatory (it's optional in IPv4)
- IPv6: supports unicast, multicast, and anycast (one to nearest), does not use broadcast.

IPv4: 192.168.0.1   IPv6: 2001:odb8:85a3:0000:0000:8a2e:0370:7334  
2001:odb8:85a3::8a2e:0370:7334

## Solutions

- NAT (network address translation) – last 25 years!
- Run both IPv4 and IPv6 (dual-stack configuration)
- Time: IPv4 imbedded, many legacy systems (time is needed to ensure compatibility)

| Feature                    | IPv4  | IPv6                                      |
|----------------------------|---|---|
| <b>Version</b>             | 4   | 6   |
| <b>Header Length</b>       | Variable (20-60 bytes)  | Fixed (40 bytes)                          |
| <b>Address Length</b>      | 32-bit  | 128-bit                                   |
| <b>Traffic Class / TOS</b> | Type of Service (TOS) (8 bits)                                      | Traffic Class (8 bits)                    |
| <b>Flow Label</b>          |   | Flow Label (20 bits)                      |
| <b>Payload Length</b>      | Total Length (16 bits)  | Payload Length (16 bits)                  |
| <b>Next Header</b>         | Protocol (8 bits)   | Next Header (8 bits)                      |
| <b>Hop Limit / TTL</b>     | Time to Live (TTL) (8 bits)   | Hop Limit (8 bits)                        |
| <b>Fragmentation</b>       | Identification (16 bits), Flags (3 bits), Fragment Offset (13 bits) | Fragmentation handled by extension header |

| Feature                      | IPv4   | IPv6  |
|------------------------------|--|---|
| <b>Checksum</b>              | Header Checksum (16 bits)                              |   |
| <b>Source Address</b>        | Source Address (32 bits)                               | Source Address (128 bits)                                       |
| <b>Destination Address</b>   | Destination Address (32 bits)                          | Destination Address (128 bits)                                  |
| <b>Options / Extensions</b>  | Options (variable length)                              | Uses extension headers  |
| <b>Padding</b>               | Ensures the header is a multiple of 32 bits            |   |
| <b>Simplified Processing</b> | More complex due to variable header length and options | Simplified processing due to fewer fields and fixed header size |
| <b>Security</b>              | Optional protocols like IPsec                          | IPsec support is mandatory                                      |

# Key Differences

|                               | IPv4                                     | IPv6  |
|-------------------------------|--|---|
| <b>Address Space</b>          | 32-bit addresses                         | 128-bit addresses                                 |
| <b>Header Length</b>          | Variable (20-60 bytes)                   | Fixed (40 bytes)                                  |
| <b>Fragmentation Handling</b> | Routers and sending hosts                | Sending hosts only, via Fragment extension header |
| <b>Header Checksum</b>        | Includes a header checksum               | No header checksum                                |
| <b>Options and Extensions</b> | Included within the header               | Uses separate extension headers                   |
| <b>Flow Label Field</b>       | No equivalent                            | Includes a Flow Label field                       |
| <b>Security</b>               | Handled by optional protocols like IPsec | IPsec support is mandatory                        |
| <b>Processing Efficiency</b>  | More complex header processing           | Simplified header processing                      |

# IPv6 Address Space

- IPv6: 128-bit address ( $2^{128}$ ) That's a lot.  
( $6.65 \times 10^{23}$  per square meter on earth\*)
- IPv6 Address Types (single host has multiple addresses assigned, each serving specific function)
  - Unicast (1:1)
  - Multicast (1:M)
  - Anycast (1:nearest)
- Address Notation
  - user lower case
  - 16-bit blocks (leading 0 in 16 bit block can be dropped)
  - :: can replace largest number of consecutive zeros, once in an address

2001:0db8:0000:0000:0056:abcd:0000:1234  
2001:db8::56:abcd:0:1234

- IPv4 mixed environment:

IPv4: 192.168.1.2  
IPv6: ::192.168.1.2  
or ::c0a8:2 (hex)

- Prefix length replaces subnet mask
  - think CIDR: IPv6 Address /prefix length

# IPv6 Address Breakdown

2001:0DB8:0000:0000:A222:B333:0000:ABCD /64

Global Prefix: 2001:DB8:0000 ISP provided Public Address

Subnet: 0000 set by local network admin

Interface ID: A222:B333:0000:ABCD

Global prefix + Subnet: /64

# In class: Activity 1

## A) Expand the following IPv6 Addresses

1. 2001:db8::1
2. fe80::
3. ::ffff:c00a:2ff
4. 2001:0db8:0:0:0:0:1428:57ab
5. ::1

## B) Compress the following IPv6 Addresses

1. 2001:0db8:0000:0000:0000:0000:0000:0001
2. fe80:0000:0000:0000:0202:b3ff:fe1e:8329
3. 0000:0000:0000:0000:0000:0000:0000:0001
4. 2001:0db8:0000:0042:0000:8a2e:0370:7334
5. 0000:0000:0000:0000:0000:ffff:c00a:02ff

# Activity 1 (continued)

C) Given the following IPv6 addresses and prefix lengths, identify the subnet prefix:

1. 2001:0db8:85a3:0000:0000:8a2e:0370:7334/64
2. 2001:0db8:abcd:1234:5678:9abc:def0:1234/48
3. fe80:0000:0000:0000:0202:b3ff:fe1e:8329/128
4. 2001:0db8:abcd:0012:0000:0000:0000:0001/56

D) For the following IPv6 addresses and prefix lengths, identify the network portion and the host portion:

1. 2001:0db8:85a3:0000:0000:8a2e:0370:7334/64
2. 2001:0db8:abcd:1234:5678:9abc:def0:1234/48
3. fe80:0000:0000:0000:0202:b3ff:fe1e:8329/64
4. 2001:0db8:abcd:0012:3456:789a:bcde:f012/56

# Subnetting IPv6: Example

Given an IPv6 address and subnet prefix, create two subnets. Determine the Network Addresses

IPv6 Address: 2001:0db8:85a3::

Subnet Prefix: /64

## Solution

### Step 1: Understand the Problem

We have an IPv6 address with a /64 prefix.

Subdividing this into 2 networks means increasing the prefix length by 1 bit (from /64 to /65).

### Step 2: Subnet the IPv6 Address

When dividing a /64 network into two /65 networks:

The first /65 network will have the first bit of the 65th position as 0.

The second /65 network will have the first bit of the 65th position as 1.

### Step 3: Determine Network Addresses

#### Network 1:

Network Address: 2001:0db8:85a3:: (first 65th bit = 0)

Prefix: /65

#### Network 2:

Network Address: 2001:0db8:85a3:8000:: (first 65th bit = 1)

Prefix: /65

Remember:

IPv6 is 128 bits

Every segment has 16 bits

# Subnetting IPv6:

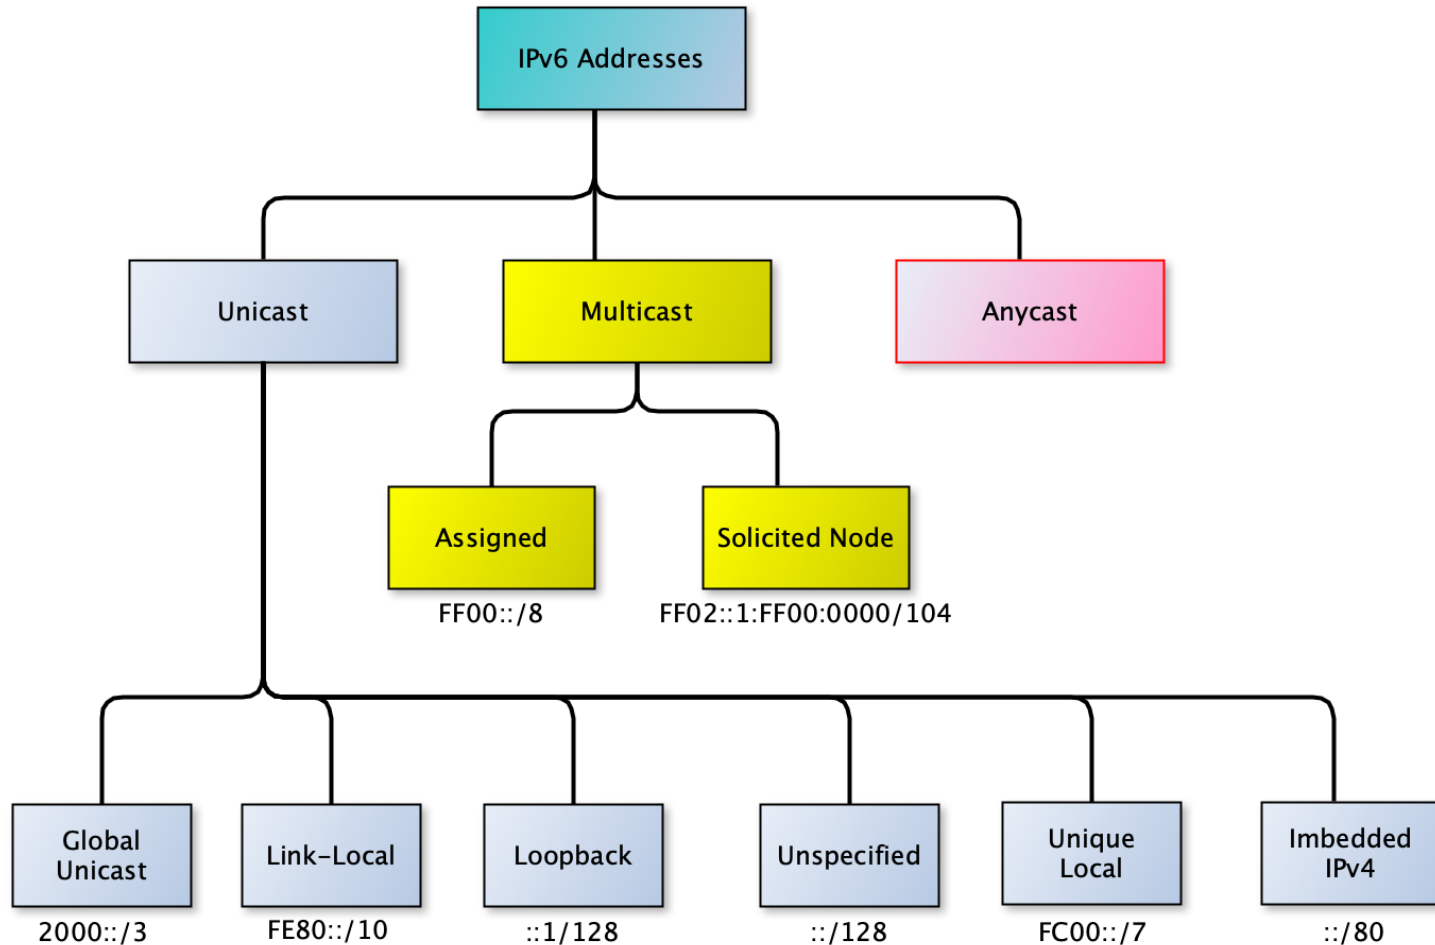

Given an IPv6 address and subnet prefix:

- Create two subnets.
- Determine the Network Addresses

Problem 1: IPv6 Address: 3001:abcd:ef01:: /56

Problem 2: IPv6 Address: 2400:dead:beef:: /48

# IPv6 Addresses

# IPv6 Addressing

- Autoconfiguration:
  - On boot, network prefix from IPv6 router on link
  - Using network prefix, autoconfigures valid global IP using MAC or private random number
- Elimination of NAT: larger address space means no shortage of addresses
- Enhanced IPsec:
  - Seamlessly integrated into IPv6 protocol stack
  - No NAT issues (secure end-to-end communication)
  - Standardization means improved interoperability between vendors

# In class: Activity 2

- View IPv6 configuration (ipconfig /all or ifconfig)
- Identify link-local address and global address
- Ping local IPv6 host:
- Ping 2001:4860:4860:8888
- Ping classmate's IPv6 address

# Moving to IPv6: Transitions

- Dual-Stack: IPv6/IPv4 node – provides complete support for both protocol versions
  - IPv6 only (IPv4 disabled)
  - IPv4 only (IPv6 disabled)
  - Dual Stack mode (both enabled)

# Moving to IPv6: Transitions

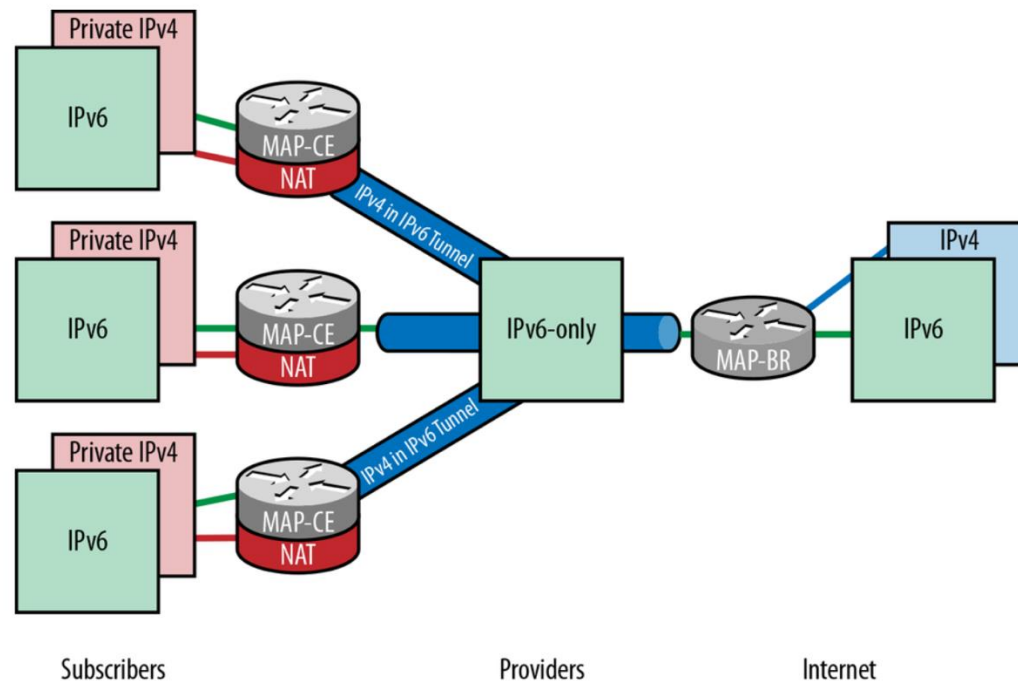

- Tunneling: Encapsulating IPv6 traffic in IPv4 packets and routing through IPv4 infrastructure

1. Marvin sends an IPv6 packet to Router 1.
2. Router 1—in this case, the tunnel entry point—encapsulates the IPv6 packet in an IPv4 header and sends it to Router 2.
3. Router 2—in this case, the tunnel exit point—strips off the IPv4 header and forwards the packet to Ford.

# Moving to IPv6: Transitions

- NAT:
  - Temp fix (hiding multiple private addresses behind one public address)

# Troubleshooting IPv6 Issues

## Common IPv6 Connectivity Issues

- **Dual-stack implementation problems:** timeouts, poor connectivity, slow connections
- **Incomplete IPv6 configuration:** everything there?
- **lack of IPv6 support in applications / devices:** Update hardware and software . . .
- **IPv6 Address Assignment:** issues with SLAAC or DHCPv6 (incorrect or inconsistent address assignment)
- **DNS Resolution Issues:** DNS servers not configured to resolve IPv6 addresses (AAAA records)
- **Transition Mechanisms Issues (6to4, NAT64):** transition between IPv4 and IPv6 can introduce latency or fail:

# Troubleshooting IPv6 Issues

## Using Windows Troubleshooter for IPv6

- Verify IPv6 Configuration: `ipconfig/all`
- Ping IPv6 Address: `ping ::1`, gateway, external address
- Check Windows firewall: is IPv6 traffic allowed?
- Check DNS Settings: `nslookup -query <hostname>`
- Check for software Conflicts: Temporarily disable third-party firewalls, antivirus software
